ACRONYMS

BF	Breastfeeding.
CI	Confidence Interval.
CDR	Crude Death Rate.
CSO	Central Statistical Organization.
ENA	Emergency Nutrition Assessment.
GAM	Global Acute Malnutrition.
HAZ	Height-for-Age-Z score.
HHs	Households.
IDP	Internal Displacement population
IYCFP	Infant & Young Children Feeding Practices.
MAD	Minimum Acceptable Diet.
MAM	Moderate Acute Malnutrition.
MDD	Minimum Dietary Diversity.
MMF	Minimum Meal Frequency.
MUAC	Mid Upper Arm Circumference.
S.D	Standard Deviation.
SAM	Sever Acute Malnutrition.
SDGs	Sustainable Development Goals.
SMART	Standardized Monitoring & Assessment for Relief & Transition.
TG	Taiz Governorate
THL	Taiz Highland.
U5	Children Under the age of five years
U5DR	Under Five Death Rate.
UNICEF	United Nation Children's Fund.
WAZ	Weight-for-Age-Z score.
WHO	World Health Organization.
WHZ	Weight-for-Height-Z score.
YHRP	Yemen Humanitarian Response Plan,
YNHDS	The Yemeni National Health Demographic survey.

DEFINITION OF TERMS

EBF	Proportion of infants 0–5 months of age who are fed exclusively with breast milk
CDR	Number of people in the total population who die over a specified period of time.
Continued breastfeeding at 1 year	Proportion of children 12–15 months of age who are fed breast milk.
Early Initiation of BF	Proportion of children born in the last 24 months who were put to the breast within one hour of birth.
HH	A group people dwelling within the same compound or unit eating from the same pot
MAD	Proportion of children 6–23 months of age who receive a minimum acceptable diet (apart from breast milk).
MDD	Proportion of children 6–23 months of age who receive foods from 4 or more food groups.
MMF	Proportion of breastfed and non-breastfed children 6–23 months of age who receive solid, semi-solid, or soft foods (but also including milk feeds for non-breastfed children) the minimum number of times or more.
U5DR	Number of children aged from birth to 5 years who die over a specified period of time in relation to the total number of children below 5 years of age in the population

EXECUTIVE SUMMARY

This report presents findings from a survey conducted by Save the Children (SC) in Taiz Governorate from 18 to 30 March 2017. The Standardized Monitoring & Assessments of Reliefs & Transitions (SMART) methodology was used. The survey was conducted in 7 accessible districts in Taiz Highland (THL) zone. Surveyed districts were AL-Mawaset, Samea, Al-Selw, Al-Misrakh, Saber Al-Mawadem, Khadeer and Al-Maafer. A two-staged cross sectional survey was conducted. The study population in the seven districts was 571,889 people living in 345 villages. A total of 563 households (HHs) and 624 U5 children were enumerated. The survey aimed to determine the nutritional status of U5 children, IYCF practices and crude mortality rate in the study population.

Prevalence of Malnutrition

Indicator		Prevalence as a percentage (95% CI)
Global Acute Malnutrition, WHZ	(<-2s.d.)	11.3 (8.7 – 14.5)
Stunting, HAZ	(<-2s.d.)	51.4 (44.2 – 58.6)
Underweight, WAZ	(<-2s.d.)	39.2 (34.0 – 44.7)

A few indicators on Infant and Young Child Feeding were explored. Early initiation of breastfeeding in the surveyed population was found to be 36% that is to say only one in every three newly born infants was receiving breastmilk within the first hour of birth. Exclusive breastfeeding rate in the population was found to be 41% thus one in every two infants aged 0 to 6 months were receiving exclusively breastmilk and nothing else from birth to 6 months. The proportion of children 12 to 15 months of age who were still receiving breastmilk at the time of the assessment was 66%. The proportion of young children who were receiving a diet with minimum diversity (minimum dietary diversity) was 9.2%, thus one in every 10 children aged 6 to 23 months old were receiving a diet of minimum quality (at least four food groups per day).

The crude death rate (CDR) is defined as the number of people in the total population who die over a specified period of time¹. Crude death rate (CDR) was assessed for a period of 90 days prior to the survey dates. CDR was found to be 0.09 deaths/ 10,000 people/ day. Similarly U5 death rate is defined as the number of children aged from birth to 5 years who die over a specified period of time in relation to the total number of children below 5 years of age in the population (based on the SMART methodology, April 2006). U5 death rate (all-cause mortality) was found to be 0.19 deaths/10000 children under five/ day for the same recall period as CDR.

The poor IYCF practices are a contributing factor high malnutrition rates in THL zone. There is need to support optimal IYCF practices, provide lifesaving interventions to support and manage acute malnutrition and provide preventative services to curb further deterioration of the current situation. It is well documented that malnutrition is the major underlying factor for 35 and 55 percent of all childhood deaths, and this situation is worse during emergencies².

¹ Measuring Mortality, Nutritional Status, and Food Security in Crisis Situations: SMART METHODOLOGY, April 2006

ACKNOWLEDGEMENTS

SC would like to express its sincere gratitude to Taiz Governorate for their unwavering support during the nutrition assessment. SC would also want to express its appreciation to the Global Affairs Canada (GAC) for funding this one year project. Our special mention goes to SC Canada office for their guidance and support. SC also expresses its gratitude to the Nutrition Technical Assessment Working Group (TAWG) made up of different partners in Yemen for their technical support. Much appreciation goes to Dr Taha Ali Abdulrahman Al-Sorori for his leadership during data collection and analysis.

INTRODUCTION

Background

Save the Children (SC) has been implementing humanitarian and development programs in Yemen since 1963. SC has a country office located in Sana'a and three Area Offices in the north (Hodeidah), centre (Sana'a) and south (Aden) of the country. SC is currently operational in 8 out of Yemen's 22 governorates: In the North Area – Sa'ada, Hodeidah and Hajjah; In the Centre Area –Sana'a and Amran; in the South Area – Taiz, Aden and Lahj. SC implements programmes in six different technical areas; child protection and child rights' governance, education, health, nutrition, water sanitation and hygiene (WASH) and food security and livelihoods.

Yemen is the poorest country in the Middle East and ranks 154 of 187 countries on the Human Development Index³. High levels of poverty, poor education and poor health outcomes have been worsened by the protracted conflict that began in March 2015 and still rages on. In March 2017 seven out of the 22 governorates in Yemen were classified to be in IPC phase 4 (an emergency level) of food insecurity. Taiz was one of the seven governorates IPC classified to be in this emergency phase. An estimated 17 million people, which is equivalent to 60% of the total Yemeni population, were reported to be food insecure and requiring urgent humanitarian assistance to save lives and protect livelihoods⁴.

Taiz Governorate is located in the southwestern part of the Republic of Yemen, bordering the Red Sea to the west, AL-Hodaidah and Ibb governorates to the north, Lahj governorate to the south, and Al-Dhale governorate to the east. Its surface area is about 10462 km². Taiz is Yemen's most populous governorate, with an estimated 3,116,000 people–11.3% of the country's population (2016 population projection based on 2004 census)⁵. About 81% of the population is rural while 19% is urban; 46.7% is male and 53.3% is female. Taiz's population

³ OCHA, Yemen humanitarian response plan 2013

⁴ Integrated Food Security Phase Classification-IPC March 2017

⁵ Central Statistical Organization (CSO). Population Projection Based on 2004 Census. Yemen

growth rate is 2.47%. Current population density is estimated at 298 inhabitants per square kilometer⁶. Administratively Taiz is divided into 23 districts. Table below shows the districts by settlement. The Map below illustrates the position of visited districts among the other districts in Taiz governorate.

Figure 1: Map of Taiz governorate showing visited districts in relation to other districts

⁶ Central Statistical Organization (CSO). Population Projection Based on 2004 Census. Yemen.

Table 1: List of districts in Taiz governorate by settlement type

Settlement Type	District	
Urban	Muzaffar Qahera Salah	
Rural	Al Taziha Saber Al Moadm Mashra'a Hdnan Al Msrakh Jabal Habashi Mawasit Al Maafr Ashammaitin Mauza'a Mawiah	Al Wazeia Al Makha Dhubab Maqbana Sharhab Al Rawna Sharhab Al Salam Khadder Same'a Aselow Hiffan

Taiz governorate is made up of two ecological zones, namely the Mountainous Zone or Highland Zone and the Lowland Coastal Plain or just the Lowland Zone. Although the governorate is characterized by diverse economic activity, the population's characteristics and living conditions differ significantly between the two ecological zones. People in the highland area engage mostly in farming, cultivating crops such as grains, vegetables, Qat and fruits as well as livestock and industry.

Taiz governorate is a heavily contested governorate among the warring parties. Many of the districts in Taiz have active fighting making them difficult to access for humanitarian workers. Taiz has the highest number of Internally Displaced Persons (IDPs) according to the latest reports from the Task Force on Population Movement.

Objectives of the assessment

Overall Objective:

- To assess the nutritional status of the children aged 6 to 59 months old, IYCF practices and mortality rates in SC supported districts (see table 1 above)

Specific Objectives:

- To determine the prevalence of acute malnutrition among children aged 6-59 months

- ii. To determine the prevalence of chronic malnutrition among children aged 6 – 59 months
- iii. To estimate the crude death rate and U5 death rates.
- iv. To assess IYCF Practices among children less than 0 – 23 months
- v. To estimate the prevalence of U5 morbidity (diarrhoea, acute respiratory illnesses, and fever).
- vi. To estimate the vaccination coverage of Penta3, Measles and Vitamin A supplementation among the 6 – 59 months children in the past 6 months
- vii. To assess household WASH practices

Justification

Due to the current protracted conflict and widespread displacements, it is a good practice and recommended to frequently monitor the prevalence of acute malnutrition. This assessment will be carried as part of a plan to measure the prevalence of malnutrition. The data obtained from this assessment will be used to inform nutrition programming, for example in calculating caseloads for acute malnutrition management and many other needs.

METHODOLOGY

Study design

A two-staged cluster cross sectional survey was conducted from 18 to 30 March 2017. The methods used, including sampling and sample size determination followed the Standardized Monitoring & Assessment of Relief & Transition (SMART) methodology⁷. The survey was conducted in 7 districts in Taiz Highland (THL) zone out of the 16 possible districts. Districts covered were AL-Mawaset, Samea, Al-Selw, Al-Misrakh, Saber Al-Mawadem, Khadeer and Al-Maafer.

Study population

⁷ SMART, Action Against Hunger-Canada, and Technical Advisory Group. (2012) Sampling Methods and Sample Size Calculation for the SMART Methodology

The total population from the 7 districts was estimated to be 571,889 people living in 20 Ozla (sub district) and 345 villages. All the households residing in Taiz at the time of assessment were eligible to be included.

Sample size calculation

ENA software was used to calculate the minimum number of HHs to be visited to obtain a statistically significant results (5% level of significance). Three sample sizes were calculated for the purpose of this survey. Sample size for anthropometric estimates, sample size for mortality estimates and sample size for IYCF indicators estimates. The largest of the three sample sizes was chosen as the number of units to be enumerated (sample size calculated based on IYCF indicators). All households reached during enumeration were included for mortality assessment. The sample size calculated for IYCF indicators was the highest and was considered as the sample size for the assessment. The calculated sample sizes for anthropometric, mortality and IYCF indicators and the parameters used during the calculations are shown in tables below. The formula used to determine IYCF sample size is shown below.

$$n = \frac{\left(\frac{Nz^2pq}{d^2(N-1) + z^2pq} \right) \times DE}{c}$$

Where:

n	Is the calculated sample size
N	The target population (68303)
z^2	Type I error (using 95% confidence level the type I error was taken to be 5% (a z-value of 1.96)
p	Proportion of an indicator of interest being evaluated, mdd at 50%
q	1 - p
d^2	Precision, a precision of 0.05 was used
DE	Design effect, DE of 1.5 was used
c	the average HH size multiplied by the expected proportion of under 2 years children among under-fives and the proportion of under-fives in population (7*0.18*0.4)

Table 2: Parameters used in the Sample Size Determination: Based on anthropometric indicators

Parameters for Anthropometry	Value
Estimated Prevalence of GAM (%)	14.5

± Desired precision (%)	3.5
Design Effect (n)	1.0
Children to be included (n)	423
Average HH Size n (n)	7.4
% Children under-5	18.4
% Non-response Households	3.0
Households to be included	356

Table 3: Parameters used in the Sample Size Determination: Based on mortality indicators

Parameters for Mortality	Value
Estimated Death Rate /10,000/day	0.3
± Desired precision /10,000/day	0.3
Design Effect (if applicable)	1.0
Recall Period in days	90
Population to be included	1,446
Average HH Size	7.4
% Non-response Households	3.0
Households to be included	201

Table 4: Parameters used in the Sample Size Determination: Based on IYCF Indicators

Parameters for IYCF	Value
Estimated Prevalence of MAD (%)	13.0
± Desired precision (%)	5.0
Design Effect (%)	1.5
Children to be included (0 – 23months)	284
Average HH Size (n)	7.4
% Children under-5	18.4
Proportion of 0-23months among U5 (%)	40.0
% Non-response Households	3.0
Households to be included	542

A total of 542 HHs was adopted as the sample size for the assessment because it was the highest among the calculated sample sizes.

Sampling Procedure

The assessment had two stages of sampling, in the first stage 30 villages were selected (a village represented a cluster). The villages to be visited were selected randomly using probability Proportional to Population Size (PPS) embedded in the ENA software. A total of 345 villages with their corresponding population sizes were entered onto ENA and 30 clusters (villages) were drawn randomly according to PPS. The number of villages sampled from each district is shown in table below:

Table 5: Number of villages sampled from each district and corresponding district population size

No.	Geographical unit (7 districts within TAIZ)	Population size	# of villages	# of Cluster Selected	Reserved
1	AL-Mawaset	119,769	83	7	0
2	Sameaa	57,093	35	2	1
3	Al-Selw	18,833	17	2	0
4	Al-Misrakh	73,548	38	4	0
5	Saber Al-Mawadem	49,232	28	2	1
6	Khadeer	141,982	75	7	1
7	Al-Maafer	111,426	69	6	1
	Total	571,883	345	30	4

In the second stage of sampling, simple random sampling (SRS) was used to select HHs. An updated list of HHs was obtained from the village leaders and in some cases from a list was constructed in the village with the help of a respectable key informant from the local village involved. Each listed household was then assigned a number and the team leader wrote the numbers on small separate papers. The small papers were put in a hat and a number was picked randomly from the hat. A number (small piece of paper) was picked with replacement after reshuffling. Numbers were picked with replacement until the team had a total of 18HHs.

Data collection instrument

Data was collected on hard copy questionnaires of semi-structured questions. An adult who could give consent (adult above 18 years of age) was the one permitted to respond. Mortality data was collected from all the selected households, irrespective of presence or absence of children under the age of five years. A recall period of 90 days was used for collecting mortality data. For child anthropometric data, weight in kilograms was measured using electronic SECA scale from UNICEF that had a tarring function "mother-baby function". Weight was taken for children wearing light clothes (excess clothes were removed such as pants or sweaters). Children less than two years of age were measured length (lying down) and those two years and above were measure height. Height was measured in cm using the standard height board from UNICEF. MUAC was measured using MUAC in cm using the standard colour coded MUAC tap from UNICEF. During data collection there was no stratification of any kind that was employed.

Training of enumerators

Enumerators attended a 7 days training on questionnaire administration and instruments calibration including role plays and field pretesting exercise. The survey had 5 teams of 4 members; 1 team leader, 3 data collectors (1 male and 3 females).The purpose of the training was to standardize the way questions were asked and the way data was recorded during data collection. Common mistakes were highlighted to minimize interviewer and or recall bias. The training also emphasized and capacitated enumerators on ethics during assessments and the expected code of conduct.

Data management

During data collection and data entry date of births were recorded as provided by the mother, some dates came in Hijri calendar and some in Gregorian calendar format. Enumerators recorded the dates as provided, after data entry web based dates converters were used to convert from Hijri to Gregorian calendar format.

Data was entered onto an excel data base. Data was transferred into ENA⁸ for analysing anthropometric and mortality data. IYCF data was exported to SPSS for analysis. In SPSS, frequencies and cross-tabulations were used to give percentages, means and standard deviations in the descriptive analysis and presentation of general household and child characteristics. Significances was defined as ($p>0.05$). The classification the nutritional status using the above indices as well as MUAC was made following the WHO classification. Statistical test for difference between two samples were carried out using test for proportions with the assumption of equal variance.

Plausibility

Anthropometric data collected during the assessment was of high quality as reflected by the plausibility checks (appendix 1) that were conducted on the data. Plausibility checks are conducted to assess the trustworthiness of the data as source of inference on the population of interest. During plausibility checks double entry of records, digit preference, selection bias (age group and sex ratios are assessed), the normality of HAZ, WAZ and WHZ scores and according to HAZ, WAZ and WHZ outlying entries. There were no double entries detected in the data set. The overall sex ratio (ratio boys/girls) equals was 1.1 with p-value = 0.119 (so, boys and girls equally represented). Percentage of values flagged with SMART flags: WHZ: 0.2 %, HAZ: 0.9 %, WAZ: 0.2 %. Age ratio of 6-29 months to 30-59 months: 0.81 (The value should be around 0.85) p-value = 0.572 (as expected).

⁸ ENA for SMART (ENA 2011 version July, 9th 2015)

RESULTS

Demographics

A total of 563 HHs were interviewed during the assessment. The average HH size (mean) was 7 individuals. 6% of the interviewed HHs were headed by females. Table below illustrates demographic variables for the interviewed HHs.

Table 6: Demographic characteristics of the interviewed HHs

Characteristic		Count n (%)
Mean Household size		6.9
Mean No. of U5 children		1.1
Household head gender		
	Man	520 (93.9)
	Woman	34 (6.1)
Household caretaker gender		
	Man	11 (2.0)
	Woman	543 (98.0)
Household caretaker Marital status		
	Married	493 (89)
	Widowed	47 (8.5)
	Divorced	6 (1.1)
	Recalcitrant	1 (0.2)
	Single	7 (1.3)
Household caretaker educational level		
	Illiterate	324 (58.5)
	Read and write	25 (4.5)
	Basic education	114 (20.6)
	Secondary education	67 (12.1)
	Higher education	24 (4.3)
Household caretaker educational status		
	Illiterate	383 (69.1)
	Literate	171 (30.9)

The overall sex ratio for the assessment was 1.1 Boys to Girls thus there was equal representation of boys and girls in the assessment. Table below illustrates the sex ratio of boys to girls in different age groups.

Table 7: Sex ratio of boys to girls among children from the surveyed HHs by age group

Age group	Boys n (%)	Girls n (%)	Total n (%)	Ratio;Boy: Girl
6-17 months	67 (54.0)	57 (46.0)	124 (22.0)	1.2
18-29 months	66 (51.6)	62 (48.4)	128 (22.7)	1.1
30-41 months	83 (59.3)	57 (40.7)	140 (24.9)	1.5
42-53 months	54 (46.6)	62 (53.4)	116 (20.6)	0.9
54-59 months	30 (54.5)	25 (45.5)	55 (9.8)	1.2
Total	300 (53.3)	263 (46.7)	563 (100)	1.1

Figure 2: The age gender structure of the interviewed HHs as a population pyramid

Malnutrition rates

During the survey the nutrition status of children 6 to 59 months old was determined. Indices including stunting rates, acute malnutrition rates and prevalence of undernutrition were explored. Stunting was defined as height for age z-score (HAZ) of less than -2SD. Children with HAZ of less than -3SD were classified as severely stunted. Children who had a weight for height z-score (WHZ) of less than -3SD or had oedema were classified as having severe acute malnutrition (SAM). Children with WHZ of less than -2SD and more than -3SD were classified as having moderate acute malnutrition (MAM). A summary measure of all the

children who had acute malnutrition WHZ of less than -2SD (SAM and MAM children) was also explored known as Global Acute Malnutrition (GAM). Children who had a weight for age z scores (WAZ) of -2SD were classified as being underweight. All the indices on malnutrition were classified using WHO 2006 growth standards.

Table 8: Prevalence of stunting by level and sex (SMART flags)

stunting level	Boys n=297 (95% CI)	Girls n=257 (95% CI)	Combined n=554 (95% CI)
stunting (HAZ <-2SD)	51.5 (43.8 - 59.1)	51.4 (42.8 - 59.8)	51.4 (44.2 - 58.6)
moderate stunting (HAZ >=-3SD and <-2SD)	30.6 (25.5 - 36.4)	33.1 (27.6 - 39.0)	31.8 (27.8 - 36.0)
severe stunting (HAZ <-3SD)	20.9 (15.2 - 27.9)	18.3 (11.6 - 27.7)	19.7 (14.2 - 26.6)

Table 9: Prevalence of acute malnutrition using WHZ scores & or oedema for classification by sex

Acute malnutrition level	Boys n=298 (95% CI)	Girls n=260 (95% CI)	Combined n=558 (95% CI)
GAM (WHZ <-2SD & or oedema)	14.1 (10.0 - 19.4)	8.1 (5.1 - 12.5)	11.3 (8.7 - 14.5)
SAM (WHZ <-3SD & or oedema)	1.7 (0.6 - 4.6)	0.8 (0.2 - 3.1)	1.3 (0.6 - 2.7)
MAM (WHZ >=-3SD and <-2SD)	12.4 (8.5 - 17.9)	7.3 (4.5 - 11.7)	10.0 (7.5 - 13.2)

Table 10: Prevalence of acute malnutrition using MUAC & or oedema for classification by sex

Acute malnutrition level	Boys n=300 (95% CI)	Girls n=263 (95% CI)	Combined n=563 (95% CI)
GAM (MUAC<125mm & or oedema)	5.7 (3.7 - 8.6)	5.7 (3.5 - 9.2)	5.7 (4.0 - 8.0)
SAM (MUAC<115mm & or oedema)	1.0 (0.3 - 3.1)	1.5 (0.6 - 3.8)	1.2 (0.6 - 2.7)
MAM (MUAC >=115mm and <125mm)	4.7 (2.9 - 7.4)	4.2 (2.4 - 7.3)	4.4 (3.1 - 6.4)

Table 11: Prevalence of underweight based on WAZ by sex

Underweight level	Boys n=298 (95% CI)	Girls n=260 (95% CI)	Combined n=558 (95% CI)
Underweight (WAZ <-2SD)	41.4 (34.7 - 48.9)	36.5 (29.6 - 44.1)	39.2 (34.0 - 44.7)

Moderate underweight (WAZ \geq -3SD & $<$ -2SD)	29.2 (22.8 – 36.5)	28.8 (23.7 – 34.6)	29.0 (25.5 – 32.9)
Severe underweight (WAZ $<$ -3SD)	12.4 (8.3 – 18.1)	7.7 (4.8 – 12.0)	10.2 (7.3 – 14.1)

The difference in stunting ($<$ -2SD) prevalence across sex was statistically insignificant ($p=0.98$). The overall stunting prevalence among children from all the interviewed HHs was 51.4%. Figure below illustrates the distribution of all the observed HAZ scores in comparison with the WHO 2006 growth standards. According to the Shapiro – Wilk test the observed HAZ distribution was normal ($p= 0.062$). The difference in GAM across sex (table above) was statistically significant ($p=0.025$). Figure below illustrates the observed WHZ scores in comparison to WHO 2006 growth standards. According to the Shapiro – Wilk test, the observed WHZ score were normally distributed ($p=0.264$). The difference in the prevalence of underweight between boys and girls aged 6 to 59 months from the interviewed HHs was statistically insignificant ($p=0.237$). According to the Shapiro – Wilk test the observed WAZ distribution was normal ($p= 0.773$). During the assessment no oedematous children were identified among the sampled HHs.

Mortality

The crude death rate (CDR), is defined as the number of people in the total population who die over a specified period of time. The CDR for the seven interviewed districts in Taiz was 0.09 deaths per 10,000 people per day (95% CI: 0.0 – 0.27) for the 3 months prior to the assessment.

For this survey U5 death rate (number of children aged from birth to 5 years who die over a specified period of time in relation to the total number of children below 5 years of age in the population) . The U5 death rate for the 3 months prior to the assessment was 0.19 deaths per 10,000 people per day (95% CI: 0.02 – 0.46).

Figure 3: Distribution of HAZ, WAZ and WHZ scores overlaid by the WHO 2006 growth standards normal curves

Child Morbidity

The proportion of children who fell ill two weeks prior to the assessment was also determined. Illnesses that were explored are diarrhoea, cough and fever. The proportion of children that reported having fallen ill from the three diseases two weeks prior to the assessment are presented in table below.

Table 12: Child morbidity profile two weeks prior to the assessment

Ailment	proportion n=621 (95% CI)
Never ill (from diarrhoea, cough or fever)	58.1 (54.2 – 62.0)
Diarrhoea	28.9 (25.4 – 32.6)
Cough or breathing difficulty	28.2 (24.8 – 31.9)
Fever	42.5 (38.6 – 46.5)

Vaccinations and Vitamin A supplementation

The proportion of children who received their due vaccinations on measles, polio and vitamin A supplementation were assessed. 90.3% (95% CI 87.6% to 92.5%) of children aged 6 to 59 months received their due vitamin A doses at the recommended time for a period 6 months. 48.7% of children aged 9 to 59 months were confirmed (from the child health cards) to have received their measles vaccination during the assessment. Using verbal confirmation from the caregiver, 87.6% (95% CI 84.6% to 90.2%) of the children aged 9 to 59 months were reported to have their measles vaccination up to date. 51.2% (95% CI : 47.0% to 55.3%) of all the assessed children were confirmed (from the child health card) to have received pentavalent3 or polio3. Using verbal confirmation from the caregiver, 89.7% (95% CI: 86.8% to 91.9%) of the children aged between 9 and 59 months were reported that their pentavalent3/polio3 vaccination was up to date.

Infant and Young Child Feeding Practices

A total of 243 children aged 0 to 24 months were assessed. Explored IYCF indicators include early initiation, Exclusive breastfeeding (EBF) which is defined as the proportion of infants 0–5 months of age who are fed exclusively on breast-milk, continued breastfeeding defined as the proportion of children 12–15 months of age who are continue to receive breast-milk, minimum dietary diversity (MDD) defined as the proportion of children 6–23 months of age who receive foods from 4 or more food groups, and minimum meal frequency (MMF) defined as the proportion of children 6–23 months of age who receive solid, semi-solid, or soft foods the minimum (recommended) number of times and minimum acceptable diet (MAD) defined as the proportion of children 6–23 months of age who receive a minimum adequate diet for the recommended number of times a day.

Table 13: IYCF indicators for the interviewed HHs

IYCFP Indicator		proportion (95% CI)
1	Early initiation of breastfeeding (n=243)	36.2 (30.2 – 42.6)
2	Exclusive breastfeeding under 6 months(n=58)	41.4 (28.6 – 55.1)
3	Continued breastfeeding at 1 year(n=38)	65.8 (48.6 – 80.4)
4	Minimum dietary diversity(MDD)(n=185)	9.2 (5.5 – 14.3)
5	Minimum meal frequency(MMF)n=185)	42.2 (35.0 – 49.6)
6	Minimum acceptable diet(MAD)(n=185)	3.8 (1.5 – 7.6)

WASH situation

All the HHs that were visited during the survey were interviewed for WASH practices. Major sources of drinking water, toilet facilities and handwashing practises were assessed. The proportion of HHs accessing water from improved sources was 68%. Improved sources of drinking water Include piped water, public taps, standpipes, tube wells, boreholes, protected dug wells and springs, and rainwater. Table 14 presents information on major WASH indicators.

Table 14: WASH situation within Interviewed HHs

Variable		Number (%)
Main drinking water source for (N=554)	Water from unprotected well	138 (24.9)
	Water network connected to House.	118 (21.3)
	Water from covered well	117 (21.1)
	Water tanker(waitate)	77 (13.9)
	Rainwater (collected to protected containers, etc.)	34 (6.1)
	Water from unprotected spring drilled well	32 (5.8)
		28 (5.1)
	Water from protected spring	5 (0.9)
	Community water supply point (Sabeel)	2 (0.4)
	Surface water (Wadi, springs, etc.)	2 (0.4)
	Bottled water(minerals or kawthar)	1 (0.2)
Water treatment methods(n=552)	Do nothing	540 (97.8)
	Boiling	4 (0.7)
	Chlorination	1 (0.2)
	Filtering with clothes	3 (0.5)
	Ceramic/ sand filters	2 (0.4)
	Alum	2 (0.4)

HHs Latrine(n=554)	siphon or bucket to a covered pit	317 (57.2)
	siphon or bucket to the outdoors	139 (25.1)
	siphon or bucket into a toilet bowl	43 (7.8)
	Pit toilet without board / not covered	19 (3.4)
	siphon or bucket into the public sewer	11 (2.0)
	Defecating in the open (in the fields, for example, etc.)	10 (1.8)
	An improved toilet hole ventilated	9 (1.6)
	siphon or bucket to an unknown place	3 (0.5)
	A toilet hole covered with a board	3 (0.5)
<hr/>		
Hand washing practice by HH caretaker(n=554)	Before meal	396 (71.5)
	Before cooking	339 (61.2)
	After toilet	268 (48.4)

The most common source of drinking water was from unprotected wells, 24.9% of the interviewed HHs were obtaining their drinking water from unprotected wells. Treatment of water before drinking was not a common practice, only 2.2% of the interviewed HHs were treating their drinking water before use. Among the interviewed HHs 85.6% were storing their water in clean containers. 48.4% of the interviewed HHs were practicing handwashing after toilet use.

DISCUSSION

The survey results indicated that the nutrition situation is poor in the 7 districts that were covered in this survey. Global acute malnutrition was 11.3%. According to the WHO classification of GAM, the nutrition situation in this area is categorised as “serious” (prevalence between 10% and 14%)⁹ which requires urgent lifesaving interventions. With such level of acute malnutrition there is need to ensure continued support for implementation of interventions to improve access to acute malnutrition treatment services for children 6-59 months. The most recent survey that was carried out in this area indicated GAM was 14.5%. The level of stunting observed falls within the very high (HAZ \leq -2SD above 40%) or critical category according to WHO⁸. Thus the survey area has a double burden of malnutrition with high levels chronic malnutrition and at the same time high levels of acute malnutrition. Though this cannot be addressed through short term intervention it shows that the problem of malnutrition is chronic and in addition to the emergency programming there is need to design intervention to address chronic malnutrition.

IYCF practices were also assessed during the assessment. The proportion of infants who were initiated early to breastfeeding (within the first hour of being born) among the assessed infants under the age of six months was 36.2% and the rate of EBF was found to be 41.4%. Though early initiation and EBF were relatively higher than the national average, there should be interventions to promote, protect and support these practices. As indicated earlier (Table 13), all other IYCF practices e.g. MAD, MDD are suboptimal and interventions should be supported to improve these practices among caregivers of children 0-23 months in the project area. Optimal IYCF practices are a key lifesaving intervention during emergencies and can contribute to prevention of malnutrition among children 0-23 months.

⁹ <http://www.who.int/nutgrowthdb/about/introduction/en/index5.html>

The CDR (total deaths/10,000 people / day) during this assessment was found to be at 0.09 (0.03 -0.27, 95% CI) and U5DR (deaths in children under five/10,000 children under five / day) was 0.19 (0.02 – 0.46, 95% CI). These results are below the emergency thresholds for Middle East and North Africa¹⁰. In 2016 based on the SMART survey conducted by UNICEF, CDR & U5DR were 0.09% & 0.28% respectively.

Evaluation of Standard deviation, Normal distribution, Skewness and Kurtosis using the 3 exclusion (Flag) procedures

	no exclusion	exclusion from reference mean (WHO flags)	exclusion from observed mean (SMART flags)
WHZ			
Standard Deviation SD: (The SD should be between 0.8 and 1.2)	0.95	0.95	0.94
Prevalence (< -2) observed: calculated with current SD: calculated with a SD of 1:			
HAZ			
Standard Deviation SD:	1.11	1.11	1.05

(The SD should be between 0.8 and 1.2)

Prevalence (< -2) observed:	51.7%	51.7%	51.4%
calculated with current SD:	53.8%	53.8%	53.4%
calculated with a SD of 1:	54.2%	54.2%	53.6%

WAZ

Standard Deviation SD:	0.95	0.95	0.94
------------------------	------	------	------

(The SD should be between 0.8 and 1.2)

Prevalence (< -2)
observed:
calculated with current SD:
calculated with a SD of 1:

Results for Shapiro-Wilk test for normally (Gaussian) distributed data:

WHZ	p= 0.506	p= 0.506	p= 0.264
HAZ	p= 0.005	p= 0.005	p= 0.062
WAZ	p= 0.649	p= 0.649	p= 0.773

(If $p < 0.05$ then the data are not normally distributed. If $p > 0.05$ you can consider the data normally distributed)

Skewness

WHZ	-0.12	-0.12	-0.17
HAZ	-0.15	-0.15	-0.17
WAZ	-0.07	-0.07	-0.01

If the value is:

- below minus 0.4 there is a relative excess of wasted/stunted/underweight subjects in the sample
- between minus 0.4 and minus 0.2, there may be a relative excess of wasted/stunted/underweight subjects in the sample.
- between minus 0.2 and plus 0.2, the distribution can be considered as symmetrical.
- between 0.2 and 0.4, there may be an excess of obese/tall/overweight subjects in the sample.
- above 0.4, there is an excess of obese/tall/overweight subjects in the sample

Kurtosis

WHZ	0.21	0.21	0.09
HAZ	0.66	0.66	-0.16
WAZ	0.24	0.24	0.11

Kurtosis characterizes the relative size of the body versus the tails of the distribution. Positive kurtosis indicates relatively large tails and small body. Negative kurtosis indicates relatively large body and small tails.

If the absolute value is:

- above 0.4 it indicates a problem. There might have been a problem with data collection or sampling.
- between 0.2 and 0.4, the data may be affected with a problem.
- less than an absolute value of 0.2 the distribution can be considered as normal.

Test if cases are randomly distributed or aggregated over the clusters by calculation of the Index of Dispersion (ID) and comparison with the Poisson distribution for:

WHZ < -2: ID=1.00 (p=0.470)
WHZ < -3: ID=1.09 (p=0.339)
GAM: ID=1.00 (p=0.470)
SAM: ID=1.09 (p=0.339)
HAZ < -2: ID=1.93 (p=0.002)
HAZ < -3: ID=2.88 (p=0.000)
WAZ < -2: ID=1.30 (p=0.132)
WAZ < -3: ID=1.65 (p=0.016)

Subjects with SMART flags are excluded from this analysis.

The Index of Dispersion (ID) indicates the degree to which the cases are aggregated into certain clusters (the degree to which there are "pockets"). If the ID is less than 1 and $p > 0.95$ it indicates that the cases are UNIFORMLY distributed among the clusters. If the p value is between 0.05 and 0.95 the cases appear to be randomly distributed among the clusters, if ID is higher than 1 and p is less than 0.05 the cases are aggregated into certain cluster (there appear to be pockets of cases). If this is the case for Oedema but not for WHZ then aggregation of GAM and SAM cases is likely due to inclusion of oedematous cases in GAM and SAM estimates.

Are the data of the same quality at the beginning and the end of the clusters?

Evaluation of the SD for WHZ depending upon the order the cases are measured within each cluster (if one cluster per day is measured then this will be related to the time of the day the measurement is made).

Time point	0.8	0.9	1.0	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9	2.0	2.1	2.2	2.3
